Outbreaks of foodborne disease caused by *E. coli* bacteria have become a serious problem. While there are many types of *E. coli* bacteria, only certain types are caused of important foodborne illness, as the harmful foodborne strain called O157:H7. These pathogenic strains of *E. coli* are found in undercooked meat, lettuce, unpasteurized milk, apple juice and contaminated well water. In food and environmental samples responsible for disease, the levels of contamination are sometimes very low. Thus, very sensitive detection methods are required.

A very sensitive assay for the electrochemical detection of *Escherichia coli* based on DNA biosensors has been designed. The electrochemical detection is performed by the specific amplification of the *eaeA* gene, related with the pathogenic activity of these bacteria. The amplification is performed by Polymerase Chain Reaction (PCR) using labelled primers with biotin and digoxigenin, obtaining a double labelled amplicon with biotin and digoxigenin in each extreme, respectively. The amplified biological material is detected by two strategies based on i) bulk-modified composite with avidin as affinity biomolecule, obtaining high selective electrodes; and ii) magneto sensors. In the first approach, the double-labelled amplicon i) is directly linked to the avidin-modified biocomposite while in the second approach ii) it is previously immobilized on magnetic beads modified with streptavidin, followed by the magnetic capture of the beads by the magneto sensor. The electrochemical detection is finally achieved by an enzyme marker, based on HRP.

The combination of the genome amplification by PCR, capture of the double-tagged amplicon and electrochemical detection using a sensitive m-GEC electrode, provide promising results compared with Q-PCR based on TaqMan probes.

This communication describes development and characterization of an electrochemical genosensing platform where genotyping of clinically relevant samples relied on an unusual hybridization strategy: the stacking hybridization.

Taking advantage from the peculiar interactions existing between two coaxially hybridized oligonucleotides, which respectively served as stabilizing oligo and allele-specific oligonucleotide (ASO) probe, this method allowed the unambiguous resolution of mismatched from matched duplexes (yes or no response).

All hybridization experiments were performed at capture probe-modified screen-printed gold arrays.1,2 Accordingly, electrochemical transduction of the hybridization events was accomplished using a specific enzyme label, which converted its electro-inactive substrate into an electroactive derivative.

While optimizing the hybridization methodology, the performance characteristics of different pairs of coaxially hybridized probes were compared. The influence of parameters such as ASO probe length, relative position of the mismatched site and strength of the stacking interactions thus emerged.

Further characterization of the stacking hybridization process through melting experiments allowed a deeper understanding of how the mutual interactions between the oligos involved in the biorecognition process influenced selectivity and sensitivity of the assay.

To prove usefulness and general validity of the genotyping methodology, application of the analytical pathway was then demonstrated for human TP53 gene.

Owing to its inherent selectivity, sensitivity and low cost, the proposed genotyping platform, implemented into an 8 electrodes array, thus represent a promising tool for the systematic screening of genes with mutational hotspots.

TESTING OF BIODEGRADABILITY OF NON-IONIC SURFACANTS USING THE INDIRECT TENSAMMETRIC TECHNIQUE COMBINED WITH A PTFE CAPILLARY TRAP

ZENON LUKASZEWSKI*, DOBROCHNA GINTER, ALEKSANDRA CHOLDERNA-ODACHOWSKA, LILIANA PIWOWARCZYK, ROBERT RYDLICHOWSKI, and BOGDAN WYRWAS

Poznan University of Technology Institute of Chemistry, Poland Zenon.Lukaszewski@put.poznan.pl

The widespread use of detergents means that complete biodegradation of their main components – surfactants – is necessary. Different tests are used for investigating biodegradability. In screening tests, an investigated surfactant is the sole source of organic carbon, and a very simple biodegradation progress control such as CO₂ production, total organic
carbon concentration or biological oxygen demand is sufficient. However in more complex cases, such as the continuous flow activated sludge test, a specific determination of the tested surfactant is necessary. This is very difficult in the case of non-ionic surfactants (NS), especially those without chromophoric groups such as oxyethylated alcohols. Use of the indirect tensammetric technique (ITT) combined with the PTFE capillary trap (PTFECT) significantly reduces such difficulties.

For NS determination, a small sample of a test effluent is pneumatically forced through a PTFECT, and the entrapped NS are eluted with ethyl acetate and determined using ITT with ethyl acetate as a monitor.

In order to demonstrate the potential of the proposed method, the biodegradability of oxyethylated alcohol C12E10 was tested under the conditions of the OCDE 301 test with activated sludge as inoculum. The concentration of C12E10 was determined daily. On the day of maximum biodegradation rate, the bacteria strain Pseudomonas fluorescens was isolated from the tested mixture. These bacteria were augmented, and the test of C12E10 biodegradation was repeated with the augmented Pseudomonas fluorescens as the inoculum. Immediate biodegradation of C12E10 was observed.

Thallium is an element which is highly toxic to humans, animals, micro-organisms and plants. The toxic effect of the element is closely related to its mobility. The main sources of thallium pollution are pyrites and lead-zinc ores. It is therefore the areas where these ores are mined and processed which are at the greatest risk of thallium pollution. For this reason the mobility of the element in soil and bottom sediment fractions and in surface water in those areas needs to be investigated. Flow-injection differential-pulse anodic stripping voltammetry (FI-DP-ASV) is an excellent tool for such investigation. FI-DP-ASV enables the thallium determination at concentrations of picomole per litre and medium exchange when the analysed soil or sediment fraction contains interferences.

The object of this work was to determine the mobility of thallium in soil and bottom sediments, as well as surface water, in an area of lead-zinc ore mining and processing near Olkusz (Poland). Several rivulets flowing in this area were investigated in terms of thallium concentration in fractions of bottom sediments, flood-plain terraces and in surface water. Sequential extraction of soil was performed in accordance with the BCR procedure. The link between ore processing and thallium concentration is clearly observable. However, the major part of thallium is contained in the primary parent matter and is basically immovable.

This work was supported by the Ministry of Science and Higher Education (grant N305 070 31/2769).

The indirect tensammetric technique (ITT) is limited in application to the determination of non-ionic surfactants (NS). This technique has been developed in order to overcome problems with the very complex tensammetric behaviour of surfactant mixtures. The lowering of the monitoring substance peak due to competitive adsorption of the investigated surfactants is the analytical signal in ITT. Usually a saturated solution of ethyl acetate is used as the monitor. Despite the limited range of application, ITT is very useful because of the widespread use of NS, their common presence in the aquatic environment, and the lack of better methods. So far saturated ethyl acetate has proved to be the best monitor. It forms a single well-shaped tensammetric peak which reacts approximately additively for different NS. No problems with surfactant mixtures are observed. Ethyl acetate reacts only to NS, while anionic surfactants are highly tolerated. However, the disadvantage of this monitor is the technically difficult stage of dissolution of ethyl acetate. This is the crucial obstacle to the automation of the whole measurement cycle.

The aim of this work was to identify another monitoring substance having the same advantages as ethyl acetate, but with better solubility in the supporting electrolyte. The expected properties are the formation of a single well-shaped tensammetric peak located at approximately −1.25 V vs SCE, and satisfactory solubility in the supporting electrolyte. Among the substances subjected to preliminary testing, two display these properties: pentanol and iso-hexanol (4-methyl-2-pentanol). The solubility of both substances in a supporting electrolyte is much higher than for ethyl acetate, and their peaks are located within the expected range. Both tested monitors responded to different concentrations of a model NS (Triton X-100). I-shaped calibration curves were recorded. Tolerance to an anionic surfactant – dodecylbenzene sulphonate – was checked.
The analytical determination of dopamine (DA) has attracted a great deal of interest due to its physiological role as neurotransmitter. The electroanalysis of DA is hindered by the presence of other biologically active compounds, such as ascorbic acid (AA). Therefore, selectivity and sensitivity are important in the development of new electrochemical sensors for DA quantification. The use of electrodes modified with inorganic redox mediator and/or conducting polymers is very promising. In this work, the voltammetric determination of DA in the presence of AA at platinum electrodes modified with poly-[3,4-ethylenedioxythiophene] (PEDOT) and Prussian Blue (PB) hybrid films is reported. The hybrid inorganic-organic coating has been prepared by a two-step method. Firstly, the PEDOT film was deposited onto electrode surface by potentiodynamic polymerisation in aqueous solution in the presence of ferricyanide ions. The obtained ferricyanide-doped polymer film was transferred in iron (III) ions containing aqueous solution, where the electrode potential was cycled from 0.6 to -0.4 V vs. SCE. During the potential cycling, PB is formed inside the PEDOT matrix. The composite modified electrode was investigated in buffered aqueous solutions by using cyclic voltammetry and square wave voltammetry. The electrocatalytic activity of the composite coating towards the dopamine oxidation has been also investigated. The composite coating showed a high electrocatalytic effect towards the dopamine oxidation in the presence of ascorbic acid. A linear dependence of the anodic peak currents from square wave voltammetry over the dopamine concentration ranging from 5 × 10^{-3} to 6 × 10^{-4} M, in the presence of 1 × 10^{-2} M AA, was obtained. A detection limit (S/N = 3) of 2 × 10^{-5} M has been also obtained. The new modified electrode could be used as electrochemical sensor for simultaneous determination of dopamine in the presence of a high amount of ascorbic acid.

stelianl@yahoo.com

Many analytical methodologies, such as electrochemical, chromatographic, were established for the determination of dopamine (DA) in real samples1-3. In this paper a voltammetric method for the determination of DA in presence of ascobic acid (AA) at platinum electrodes modified with poly-[3,4-ethylenedioxythiophene] (PEDOT) and Prussian Blue (PB) hybrid films is reported. The hybrid films have been prepared by potentiodynamic polymerisation of EDOT in aqueous solution in the presence of ferricyanide ions, followed by potential cycling in iron (III) ions containing aqueous solution. By this procedure a hybrid PEDOT-PB coating is obtained. The results obtained through this electroanalytical method were validated and compared to analytical data obtained by high liquid performance chromatography.

The structure of oligonucleotides (ODN’s) corresponds to their properties and behavior in organisms. This work deals with the study of electrochemical and chromatographic behavior of ODN’s in relation to sequences of nucleic acid bases in the ODN chain. Twenty ODN nonamers with different sequences of adenine (A) and cytosine (C) but with the same ratio of A:C (3:6) were investigated by high performance liquid chromatography (HPLC) with UV/Vis detection and by linear sweep voltammetry (LSV) and/or elimination voltammetry with linear scan (EVLS)1-3. In electrochemical methods our interest was focused on the reduction signals of A and C measured at mercury electrode, in separation method on retention times of ODN. Both electrochemical and chromatographic data obtained were consequently evaluated by artificial neural network (ANN). We constructed ANN models using different inputs including selected points of LSV or EVLS curves (peak heights of separated reduction signals of A and C or differences of reduction A and C potentials from EVLS curves) and retention times from HPLC measurements. Moreover we used supplementary parameters such as extinction coefficients at 260 nm, melting points, AH and AS of the stacking effect4-6. The best results were obtained from the model with the following inputs: 50 points from LSV curve taken at reference scan rate 200 mV s−1, retention times and all supplementary parameters.

Quantitative non-ionic surfactant determination is a complex analytical problem as various composite mixtures, wastewaters, sewage sludges, etc. contain mixtures of their isomers, homologues and oligomers. For detection polyoxyethylated alkylphenols and their degradation products in various objects different separation techniques with subsequent detection are used. To this end, spectrophotometry, solid-phase extraction with high-performance liquid chromatography and fluorescence, thin layer, gas chromatography, chromato-mass-spectrometry are most often employed. Lately, multi-sensor systems with multivariate calibration technique ("electronic tongue") have been employed for fast qualitative and quantitative analysis of multi-component solutions. The basic requirements to an array sensor are a low selectivity and a high cross-sensitivity.

Samples of polyoxyethylated nonylphenols
C₉H₄₃(C₂H₄O)ₘH (m = 10–100) with a purity of 96–98 % were investigated. Compounds of polyoxyethylated nonylphenols with barium and tetraphenylborate ions (for example, nonylphenol-12-Ba-tetraphenylborate) were used as electrode-active compounds of membranes sensitive to non-ionic surfactants.

Low selectivity, high cross-sensitivity of surfactant sensor, and also identity of their electrochemical and transport parameters are a basis for designing multi-sensor systems for determination of homologous non-ionic surfactants in various objects (model mixtures, artificial polluted natural waters).

Analytical signals from non-ionic surfactant sensor arrays were processed by partial least-squares algorithm (PLS) and artificial neural networks (ANN) with back propagation of errors. At PLS processing the responses from surfactant sensor arrays were randomly parted into a set for training (to create a model) and a reference one for checking its forecasting capacity. To employ the artificial neural network technique the data were randomly splitted into calibration, monitoring and validation sets. Three-layered neural networks were used. The number of neurons in the input layer corresponded to the number of sensors in the array. The concentration of non-ionic surfactants, for example, in the three-component model mixture ranged from 1×10⁻⁵ to 2.2×10⁻³ mol l⁻¹ for nonylphenol-10, 1×10⁻⁵ – 2×10⁻³ mol l⁻¹ for nonylphenol-30, 1×10⁻⁵ – 3×10⁻³ mol l⁻¹ for nonylphenol-40 at different component ratios. The mean relative error of homologous non-ionic surfactant detection was 7 to 9 % for PLS and 3 to 4 % for ANN. The results of neural network training can be used for analysis both three-component model mixtures and two- component model mixtures.

The possibility of designing of surfactant sensor arrays for separate definition of homologous polyoxyethylated nonylphenols in two-, three-, four-component systems (model mixtures and artificial polluted natural waters) is shown. The least relative errors of detection were obtained for ANN.

A silver based carbon paste electrode was developed for use as detector in ion chromatography (IC) for the sensitive determination of iodide in real samples. Micro and nanoparticles of silver were investigated for different electrodes fabrication.

The iodide assay was based on ion chromatography with amperometric detection (IC-AD) at a silver composite electrode polarized at +0.080 V versus Ag/AgCl. Free iodide and organoiiodide compounds were studied. The detection process was characterized by studying the redox behavior of iodide ions at both silver and silver composite electrodes by cyclic voltammetry. The presence of iodide ions in solution was found to considerably facilitate metallic silver oxidation, with response currents directly related to iodide concentration. The calibration curve at the selected silver composite electrode was linear in the concentration range comprised between 0.635–63.5 µg L⁻¹ iodide. The relative standard deviation (RSD) for successive injections was below 3 % for all iodide standard solutions investigated. The limit of detection (LOD) was 0.47 µg L⁻¹ (3.7 nmol L⁻¹) for an injection volume of 20 µL, i.e. 74 fmol injected. The IC-AD method was successfully applied to the determination of iodide in complex real samples such as table salts, sea products and iodide bound drug compounds. The analytical accuracy was verified by the assay of iodide in milk powder from a iodide Certified Reference Material (CRM) BCR 150.

monica.moreno@uam.es

Since its introduction in stripping analysis1, the bismuth film electrode (BiFE) has been accepted in many electroanalytical laboratories worldwide. BiFEs have found a wide range of application in anodic stripping voltammetry, potentiometric stripping analysis as well as in cathodic adsorptive stripping voltammetry for the determination of some metals. On the other hand, its application for the determination of organic compounds has been much less studied2.

In this communication, a square wave cathodic voltammetry (SWCV) procedure for herbicides determination at an ex situ plated BiFE is described. Different herbicides with reductive moieties, emphasizing in the triazine derivatives, were subjected to study. Carbon-based substrates have been studied for the preparation of ex situ bismuth film electrodes as well as the influence of relevant parameters upon the bismuth film formation (plating solution, deposition potential and deposition time).

The use of bismuth film electrode present advantages over the plain substrate electrodes such as low reduction overpotential and good stability for the electroanalysis of herbicides in acidic media even in the presence of oxygen and could be a good alternative to the toxic mercury-based electrodes.

SENSOR BASED ON ELECTROSPUN NYLON NANOFIBERS

SAVERIO MANNINO*, MATTEO SCAMPICCHIO, and NATHAN S. LAWRENCE  

Dept. of Food Science and Microbiology, Milan, Via Celoria 2, 20133
saverio.mannino@unimi.it

A web-like membrane consisting of nylon nanofibers, prepared by electrospinning, was used to produce an electrochemical biosensor for the sensible sensing of glucose1. Glucose oxidase was immobilized (1) by physical adsorption on the platinum electrode surface, (2) by physical adsorption through the nylon net, and (3) by chemical bonding between the enzyme and the membrane, with glutaraldehyde as a crosslinker. In all the three set-ups, the advantages arisen by use of the nylon net were evident. The nylon nanofiber net exhibits an high surface to volume ratio compared with the usual thick nylon support. This allows unique chemical features that can be summarized as: (a) excellent support properties which prevent leakage of the enzyme; (b) selective physisorption of...
interpherents (such as polyphenols) by changing the protonation of nylon amine group, (c) prevention of the electrode passivation, (d) enhanced biosensors’ longevity. The advantages of the new nanofibers strip-coated biosensor will be discussed via the electrochemical sensing of glucose in real food matrices.

We thank Cariplo’s Foundation.

The miniaturization of amperometric chemical analyzers involves the dimensional reduction of electrodes to the micrometer scale. To generate stable potentials and to obtain precise measurements, high-sensitivity electronic circuits are required. The low temperature cofired ceramics (LTCC) technology has been widely applied to the production of multilayer printed circuit boards due to its excellent electrical, mechanical and thermal properties. Its compatibility with serigraphic techniques and its fabrication process enable the aggregation of several layers to obtain multilayer circuits, which results in high-density boards of elevated complexity and small size. In this work, the development of a microcontroller-based potentiostat using LTCC technology is presented (see figure 1). Since the potentiostat is based on a microcontroller, several amperometric techniques can be applied (cyclic voltammetry, differential pulse voltammetry, square-wave voltammetry, etc.). The instrument was designed to work in four current ranges to improve sensitivity at different intensity levels. Results showed a high signal to noise ratio with a base line of ±0.5 nA, comparable with commercial instruments.

Since the LTCC technology permits the fabrication of complex three-dimensional structures, microfluidic systems can be easily developed and integrated with electronics to obtain real micro total analysis systems (µTAS).

GENOSENSOR FOR SARS VIRUS DETECTION BASED ON GOLD NANOSTRUCTURED SCREEN-PRINTED CARBON ELECTRODES
GRACIELA MARTÍNEZ-PAREDES, M. BEGOÑA GONZALEZ-GARCIA, and AGUSTÍN COSTA-GARCIA*

Departamento de Química Física y Analítica, Universidad de Oviedo. 33006, Oviedo (Asturias), Spain. costa@fq.uniovi.es

The present work describes the design of a genosensor for a sequence of the SARS virus using gold nanostructured screen-printed carbon electrodes (SPCEs) as transducers.

SPCEs are in-situ modified with gold in order to get nanostructured surfaces by applying a constant current intensity of ~5 µA for 2 minutes using a 0.1 mM AuCl₄⁻ acidic solution. The nanostructured obtained following this methodology is showed in Fig. 1.

The design of the genosensor consists on the immobilization of thiolated probe strands over the surface, and after a blocking step, hybridization with biotin labeled target strands is carried out. Then, streptavidin labeled with alkaline phosphatase is used to catalyze an enzymatic reaction that leads to the analytical signal; an electrochemical process of silver¹.
Following this methodology, SARS virus targets can be determinated in a quantitative range from 5 pM to 100 pM. The use of these gold nanostructured surfaces improves the sensitivity obtained with continuous gold surfaces with less consumption of reagents.

This work has been supported by Spanish Project: BIO2006-15336-C04-01.

AS(III) QUANTIFICATION BY SQUARE WAVE ANODIC STRIPPING VOLTAMMETRY AT A PLANAR SILVER ELECTRODE

SANDRA P. MÉNDEZ CORTÉS, C. A. GALÁN VIDAL*, J. A. RODRÍGUEZ, G. A. ÁLVAREZ ROMERO, M. E. FAZ HERNÁNDEZ, and M. HERNÁNDEZ CRUZ

Universidad Autónoma del Estado de Hidalgo, Centro de Investigaciones Químicas. Carretera Pachuca Tulancingo Km 4.5, 42184 Mineral de la Reforma, Hidalgo, México galanv@uaeh.edu.mx

Arsenic is a toxic element which is known to be carcinogenic. Arsenic is found in a wide variety of chemical species throughout the environment and can be readily transformed by microorganisms, changes in geochemical conditions, and other environmental processes. While arsenic occurs naturally, it can be found as consequence of a variety of industrial applications, including leather and wood treatments, and pesticides.

Based on the fact that water consumption is the most important source for Arsenic poisoning, the World Health Organization has established 10 mg L\(^{-1}\) as the provisional concentration guideline for total arsenic concentration in drinking water. Nevertheless, in many countries this concentration has been overcome, which is found to be related with adverse effects to population health.

Looking for a simple, affordable, sensitive and easy-to-implement quantification alternative for in-situ analysis of arsenic, diverse electrochemical methods based on anodic stripping voltammetry (ASV) have been recently reported. In spite of the great advantages of arsenic analysis by ASV, some disadvantages are distinguished, like the toxicity or the expensive cost of working electrodes (Hg, Au and Pt).

In the present study an electrochemical assay for As(III) quantification using square wave anodic stripping voltammetry at silver screen-printed electrodes is presented. The planar strips demonstrate a good behavior even without stirring the plating solution during the deposition process and in presence of dissolved oxygen. The detection limit was 10 µg L\(^{-1}\) and the linearity range from 19 to 300 µg L\(^{-1}\). The effect of the most important ion interferences (Cl\(^{-}\), Hg\(^{2+}\), Pb\(^{2+}\) and Cu\(^{2+}\)) on stripped signal is also described. The proposed electrodes demonstrated to be suitable for in-situ As(III) analysis.

DETERMINATION OF GUANOSINE 5‘-MONOPHOSPHATE BY SQUARE WAVE VOLTAMMETRY WITH A MODIFIED GOLD ELECTRODE
LAURA MORA, PEDRO HERNÁNDEZ, JOSE VICENTE, and LUCAS HERNÁNDEZ*
Dep. Química Analítica, Facultad de Ciencias, Universidad Autónoma de Madrid, 28049 Madrid, Spain
lucas.hernandez@uam.es

The aim of the present work was the study of electrochemical behaviour and the subsequent determination of the nucleotide guanosine 5‘-monophosphate (GMP) by square wave voltammetry (SW). For these studies a modified gold electrode was used. First, a modification with an organo-sulfur compound was made, 1,2-ethanedithiol (EDT), which acted as a spacer and it spontaneously bonded to the surface of gold electrode (Au-EDT). Then, the electroactive surface of electrode was increased with gold nanoparticles (AuNPs), producing a spontaneously chemistry adsorption with the sulphur compound (Au-EDT-AuNPs). The formation and caracterization of the nanoparticles solution were realized by UV-VIS spectroscopy and an Atomic Force Microscopic (AFM). The complementary nucleotide of GMP with an atom of sulphur in its structure (4-amino-2-mercaptopirymidine, TC) was utilized for the detection and quantification of GMP; a spontaneous bond between complementary nucleotide and gold nanoparticles was formed, and the modification of gold electrode was finished. For successive studies the totally modified gold electrode was used and was denoted as Au-EDT-AuNPs-TC.

When the modification of electrode was optimized, the electrochemistry study and optimization of the conditions of measurement were realized for the direct determination of GMP by square wave voltammetry.

The authors thank the Spanish Education Ministry for financial support (Project CTQ2004-08142/BQU) and a grant scholarship to Laura Mora (AP2005-0266).

H2O2 DETERMINATION AT IRON-RICH CLAY MODIFIED ELECTRODES
CHRISTINE MOUSTY*, KHALED CHARRADI, CHANTAL GONDRA†, and JOCELYNE BRENDEL
aLaboratoire des Matériaux Inorganiques Université Blaise Pascal CNRS UMR-6002 63177 Aubière cedex (France), bDépartement de Chimie Moléculaire Université Joseph Fourier CNRS UMR-5250 38041 Grenoble cedex 9 (France), †Laboratoire de Matériaux à Porosité contrôlée ENSC Université de Haute Alsace CNRS UMR-7016 68093 Mulhouse cedex (France)
Christine.MOUSTY@univ-pauclermont.fr

Clay modified electrodes (CME) have been studied extensively because of the ion exchange properties of the clays, their layered structure and their chemical stability. The major constituents of most common smectite clays are aluminum and magnesium. But natural clays are never pure, they always contain small amount of other elements, i.e. iron. These trace elements can affect the response of CME with an electrocatalytic behavior. For instance, Oyama and Anson reported that structural iron sites could mediate the reduction of hydrogen peroxide 1. However the proposed redox activity of iron in CME has always involved adsorbed electroactive species as charge mediators (Ru(NH3)63+, Fe(bpy)33+, MV2+)2−3. Electro-luminescence experiments confirmed that iron species contained in the clays can mediate an electron transfer4,5.

In this study, we investigated the electrochemical properties of several ferruginous clays, either natural or synthetic. Three different conditions have been tested at the CME for the reduction of H2O2:

a) in acidic medium without redox mediator,
b) in neutral medium (pH 8) with adsorbed MV2+ as a charge shuttle,
c) in neutral medium (pH 7) with absorbed Hemoglobin as a biocatalyst.

The resulting CME were characterized by cyclic voltammetry in the presence or not of H2O2 and finally the calibration curves were recorded under amperometric conditions. The results will be discussed in relation to the clay properties, in particular the iron amount present in their structure and its structural sites.

This work is supported by the CMCU (06/S1207) et MIRA 2007.

Boron doped diamond (BDD) is a novel and versatile electrode material, which has gained popularity in a variety of electrochemical applications2-5. BDD thin-film electrodes possess excellent electrochemical properties, such as extreme hardness, low and stable background current over a wide potential range, microstructural stability at extreme cathodic and anodic potentials, high current densities, good responsiveness for many redox analytes without pretreatment, and resistance to electrode fouling2.

Nitrophenols coming from pesticide degradation, car exhausts, and industrial wastes are listed as priority pollutants by the US Environmental Protection Agency. They are considered to be potentially carcinogenic and mutagenic. Pesticides based on simple nitrophenols are used as growth stimulators in agriculture2. Moreover, 2,4-dinitrophenol (2,4-DNP) is a suitable model of nitrated explosives2. 2,4-DNP has been determined at BDD film electrode (Windsor Scientific, UK) by differential pulse voltammetry. The influence of pH at voltammetric behavior of 2,4-DNP was investigated using electrochemical reduction and oxidation in Britton-Robinson buffer over a pH range of 2–12. The concentration dependences were measured under optimum conditions. The voltammetric behavior of 2,4-DNP has been compared with 2-nitrophenol and 4-nitrophenol.

POLYMER – IONIC LIQUID ELECTROLYTES FOR ELECTROCHEMICAL GAS SENSORS

MARTINA NÁDHERNÁa,b, FRANTIŠEK OPEKARb, and JAKUB REITERR*

a,b, FRANTIŠEK OPEKARb, reiter@iic.cas.cz

Room temperature ionic liquids attract the attention thanks to their excellent properties: non-volatility, high conductivity, liquidity in wide temperature range, high thermal stability (up to 400 °C) and low toxicity5. Especially for electrochemical gas sensors their high electrochemical stability is highly appreciated6.

Our recent research is aimed at development of new binary systems polymer-ionic liquid serving as an electrolyte for electrochemical gas sensor for NO2. Previously used electrolytes were usually ternary systems polymer-aprotic solvent-salt3,4, while now is the function of embedded solution of salt in a solvent substituted with a hydrophobic ionic liquid based on 1-methylimidazole. We have combined several ionic liquids with various methacrylate polymers forming elastic, homogenous and long-term stable electrolytes.

Experimental
Following monomers or macromonomers (2-hydroxyethyl methacrylate HEMA, poly(ethylene glycol) methacrylate PEGMA and poly(ethylene glycol) methyl ether methacrylate PEGEMA – all from Sigma-Aldrich) and ionic liquids (1-butyl-3-methylimidazolium hexafluorophosphate BMIPF6, 1-butyl-3-methylimidazolium tetrafluoroborate BMIBF4 and 1-ethyl-3-methylimidazolium tetrafluoroborate EMIBF4 – all prepared following literature1,5,6) were combined.

Polymer electrolytes were prepared by direct, thermally initiated radical polymerization (150 min at 80 °C) of the initial liquid mixture containing the monomer, ionic liquid and polymerization initiator (2,2′-azobis(isobutyronitrile). The polymerization was carried out in a cell formed of polypropylene plate, packing distance frame (silicone rubber) and glass plate.

Electrochemical characterization of prepared electrolytes was performed on a potentiogalvanostat PGSTAT 30 (Eco Chemie, The Netherlands) including the FRA-2 module for impedance measurements.

Results and discussion
The first objective was to find chemically compatible pair of a monomer and a strongly polar ionic liquid. Therefore more polar monomers containing either -OH group and/or (CH2CH2O)n units in the structure were employed.

The combinations PEGEMA-BMIPF6 and PHEMA-BMIBF4 form samples with suitable mechanical properties allowing both manipulation and electrochemical tests such as impedance and voltammetrical measurements.

Impedance measurements showed a reasonable ionic
Fig. 1. Dependency of conductivity on reciprocal temperature of PEGMEMA-BMIPF₆ electrolyte (43:57 mol.%) and neat BMIPF₆.

Conductivity of PEGMEMA-BMIPF₆ electrolyte (2.4×10⁻⁴ S cm⁻¹ at 20 °C). Fig. 1 shows the relationship between conductivity and temperature of a polymer electrolyte and neat ionic liquid.

Voltammetrical measurements on a platinum electrode showed a broad accessible electrochemical window, especially in the case of electrolytes with PEGMEMA polymer. The absence of a hydroxyl group ensures the electrochemical stability from −2.3 to 2.5 V vs. Cd-Cd²⁺ making the electrolytes perspective also for lithium-ion batteries.

Subsequently, the electrolytes characterized above will be tested in an electrochemical sensor designed in previous research³,⁴.

ONE-STEP ENCAPSULATION OF BIOMOLECULES IN ELECTROGENERATED SOL-GEL FILMS FOR BIOSENSING APPLICATIONS

O. NADZHAFOVA, M. ETIENNE, and A. WALCARIUS*

Laboratoire de Chimie Physique et Microbiologie pour l’Environnement, UMR 7364, CNRS - Nancy University 405, rue de Vandoeuvr, F-54600 Villers-lès-Nancy, France Walcarius@lcpme.cnrs-nancy.fr

Sol-gel electrochemistry has gained great popularity in the past decade, mostly because of the ease of formation of silica and organo-silica films with tailor-made properties that can be advantageously exploited for several applications when coated on a suitable electrode surface¹. The usual way to get such films involves either dip- or spin-coating a sol-gel medium containing the appropriate (organo)alkoxysilane precursor(s), which are hydrolyzed and (co)condensed on the electrode surface. Such film-modified electrodes have found applications in various fields including electroanalysis and sensors, electrocatalysis, or bioelectrochemistry⁴.

Some years ago, Shacham and co-workers have developed a new and elegant electrochemically-driven deposition method for getting sol-gel thin films on conducting substrates⁵. The approach is based on altering the surface pH by applying a suitable potential to an electrode immersed in a sol-gel medium, inducing thereby the catalysis of the condensation process thus enhancing the rate of film deposition⁶. This work points out that electrogeneration of silica gel films on glassy carbon electrodes can be applied to immobilize biomolecules – hemoglobin (Hb) or glucose oxidase (GOD) or both of them in mixture – without preventing their activity. These proteins were physically entrapped in the sol-gel material in the course of the electro-assisted deposition process applied to form the thin films on the electrode surface. Successful immobilization of proteins was checked by various physicochemical techniques. Hb entrapped in the silica thin film displayed an electrocatalytic behavior towards O₂ and H₂O₂ in solution, respectively in the mM and mM concentration ranges. Immobilized GOD kept its biocatalytic properties towards glucose. Combined use of these two proteins in mixture has proven to be promising for detection of glucose in solution via the electrochemical monitoring of oxygen consumption (decrease of the oxygen electrocatalytic signal)⁷.

THE DETERMINATION OF DIFFUSION COEFFICIENT OF MONOSACHARIDS WITH ELECTROCHEMICAL MICROSCOPY
LIVIA NAGY, GERGELY GYETVAI, and GEZA NAGY
University of Pécs, Department of General and Physical Chemistry, 7624 Pécs, Ifjúság útja 6, Hungary
lnagy@ttk.pte.hu

The diffusion coefficient of carbohydrates in different media is an important parameter in several areas. High numbers of methods are available for measuring it. Several of them use electrochemical detection.

A simple method, based on special capability of Scanning Electrochemical Microscopy (SECM) for the accurate measurement of diffusion coefficient has been worked out in our laboratory.

It is based on detecting the concentration – time transients with appropriate electrochemical micro-sensor positioned at the close vicinity of a miniature dose source device. At given time \( t_i \) a small dose of the investigated species is introduced. The \( \Delta t_{\text{max}} = (t_{\text{c,max}}-t_i) \) value and the distance \( d = x + \Delta x_n \) between the source and the detector microelectrode are used for calculation of \( D \). While the original set distance \( x \) can not be accurately measured in the micrometer scale, the tip travel distance \( \Delta x_n \) of the microscope is well defined. Collecting a few \( \Delta t_{\text{max}} - (x + \Delta x_n) \) data pairs reliable value of the diffusion coefficient can be obtained. The procedure is simple and does not require knowing the dose size introduced.

In the work, to be presented the basic principle of the new method will be presented, and the values obtained with it will be compared with diffusion coefficient values obtained using conventional electrochemical methods. In the experiments micro size copper SECM tip, enzyme sensor, and conventional size electrodes were used. Diffusion coefficients of glucose arabinoise and other monosaccharide were measured.

The authors would like to thank Hungarian Scientific Research Fund for financially supporting this research with grant T 049502.

BIOSENSORS AND ELECTROCHEMICAL DETECTION TECHNIQUES FOR CLINICAL DIAGNOSIS
LIVIA NAGY and GEZA NAGY*
University of Pécs, General and Physical Chemistry, 7624 Pécs Ifjúság útja 86, Hungary
g-nagy@ttk.pte.hu

Recently a new measuring method has been worked out in our laboratory. The so called periodically interrupted amperometry (PIA) was proved very useful in lowering the detection limit of membrane coated electrodes, like amperometric biosensors.

As it is well known, the amperometric enzyme electrodes are made of a voltammetric base sensing element and different layers -among them enzyme containing reaction layer-coating its surface. In conventional amperometry the electrode potential kept constant, and the current generated by the electrode reaction is detected.

The concentration of electroactive species formed in the enzyme catalysed reaction is decreased by the continuous action of the electrode process. In this way the stationer layer at the surface of the sensing element gets more or less depleted.

It was expected, that periodic interruption of the electrolysis, would allow time for reloading the layer at the close vicinity of the sensing element. This could result in higher current and lower detection limit in case of an enzyme sensor.

In our presentation the basic principle of the PIA method will be introduced. In the experimental work to be presented glucose and putrescine measuring enzyme electrodes were prepared with three different stationary layers on their surface.

Platinum disc electrodes were used for preparation of the enzymatic working electrodes. PIA measuring program was applied and optimized, selecting the optimal measuring \( (t_M) \) and resting \( (t_R) \) time periods and the data collecting parameters.

Conventional amperometric detection and PIA detection were compared. The signals obtained with the optimized PIA program was much higher than the current obtained with the

CARBON PASTE ELECTRODE MODIFIED WITH COAL

ZUZANA NAVRÁTILOVÁ*, BOLESLAV TARABA, and ROMAN MARŠÁLEK

Dep. of the Chemistry, Faculty of Sciences, University of Ostrava, 30. dubna 22, 701 03 Ostrava, Czech Republic
zuzana.navratilova@osu.cz

The electrochemical properties of coals have been mostly studied by means of measurement in the coal slurries in electrolytes. Carbon paste electrode modified with carbonaceous materials (eg. activated carbon) has been also used for this purpose.

Carbon paste electrode (CPE) with mixed coal was prepared in order to find another possibility to investigate coals or carbonaceous materials. Samples of the used bituminous coal were from Ostrava-Karvina Coal Mines District. They were already characterized by proximate, ultimate as well as micropetrographic analyses.

The electrode was prepared by procedure similar to preparation of clay modified CPE. The prepared electrodes were tested as to their mechanical properties and potential range in various electrolytes (acetate buffer pH 3,6, HCl, KCl, and NaOH (all 0,1 mol l−1)). The potential ranges of the coal modified electrodes were broader in all the tested electrolytes in comparison with the unmodified CPE, especially in the positive potential direction. Cyclic voltammetry of ion pair [Fe(CN)₆]₃⁻/⁴⁻: exhibited low current values. An influence of coal particle size on the electrochemical behaviour of the coal CPEs was studied, too.

Deposition of Hg film on the surface of the coal CPE showed possibility to use it either as a substrate for metals deposition or as a means for study of the sorption properties of coals.

The work was supported by the Grant Project No. IAA301870801, Grant Agency of the Academy of Sciences of the Czech Republic.

The important features of biofuel cell are the ability to convert chemical energy to electricity with high efficiency, at room temperatures and under conditions close to physiological. Monoolein liquid-crystalline films is a convenient matrix to immobilize biocatalysts at the electrode surfaces in their active form. The lipidic cubic phase can be characterised as a curved, non-intersecting bilayer with two unconnected water channels. Monoolein (MO) is an example of a lipid forming such a phase. It is highly viscous, transparent and at hydration over 20 % is stable in contact with water. Doping MO with 1,2-dioleoyl-sn-glycero-3-phosphate increases the shear strength of the MO/H₂O cubic phase and makes the aqueous channels walls anion allowing for more stable immobilization of cationic mediators inside the cubic phase due to electrostatic interactions. Using the monoolein cubic phase for hosting the enzymes allowed also to avoid any additional separating membranes in the biofuel cell, keeps the enzymes active and close to the electrode surface. In our membraneless biofuel cell (BFC) glucose oxidase and laccase were the anodic and cathodic catalyst, respectively, the bioanode was glassy carbon modified with the cubic phase containing cationic mediators inside the cubic phase and laccase from Cerrena unicolor. The maximum power density was 7 µW cm⁻². To eliminate leaching of the mediators to the solution and improve current and power densities of the cell, selected mediators were bound covalently or adsorbed on single walled carbon nanotubes (SWNTs) forming a conductive network in the cubic phase film.

A new arrangement of silver amalgam paste electrode1 (AgAPE) was developed for the voltammetric determination of 4-nitrophenol (4-NP). Due to easy surface renovation by simple procedure, the electrode was found to be useful for the determination of nitrated phenolic compounds in waste water. The electrode showed good reproducible results for 4-NP with relative standard deviation (RSD) 2.1%. The reproducibility was also found good both in drinking water and river water with RSD 3.4% and 4.8%, respectively, without employing regeneration potential. The effect of electrode regeneration on peak current height was studied. The regeneration of electrode improved peak current stability with RSD 1.1%. Under the optimized regeneration potential the peak current stability improved for 4-NP in drinking water but in river water it deteriorated which may be due to the presence of some other interfering substances. Some passivation has been observed for 2-methyl-4,6-dinitrophenol indicating that the passivation is connected with the properties of compounds. Furthermore, fairly good reproducibility (RSD lower than 10%) of surface renovation has been observed. Under optimized condition the reduction peak currents were linear with the concentration of 4-NP from 4×10⁻⁷ to 1×10⁻⁴ mol L⁻¹ with the correlation coefficient of R² = 0.9997. The limit of determination for 4-NP at AgAPE was 3×10⁻⁹ mol L⁻¹. The determination of 4-NP at AgAPE was carried out in model samples of drinking and river water and the limit of determinations were 2×10⁻⁸ and 3×10⁻⁹ mol L⁻¹, respectively.

NEW TYPES OF MINIATURIZED (MINI- TO NANO-VOLUME) ELECTRODES, CAPILLARY OR PLASTIC- TIP SENSORS AND PORTABLE SYSTEMS, BASED ON MERCURY, AMALGAMS, COMPOSITE OR PASTE AMALGAMS, ETC

LADISLAV NOVOTNÝ

University of Pardubice, Faculty of Chemical Technology, nám. Čs. Legií 565, 532 10 Pardubice 19, Czech Republic nvt.i@seznam.cz

Sensors/electrodes based2-5 on mercury, amalgams, solid or mercury modified amalgams, etc., occupy an important position among the working electrodes as to trace analysis3-5 and study of bioactive species4. Recent development5-9 of the mentioned stationary, renewed stationary or (time-dependent) controlled-size electrodes has brought suggestion of numerous new types of useful designs and applications concerning, e.g., the miniaturized electromechanically renewed hanging (stationary) mercury drop HMDE/SMDE electrodes5-8, meniscus or hemisphere sensors, compressible/expansible electrodes5, the sensors based on the mercury modified solid amalgams7-9, composite or paste amalgams5 and materials of the analogous consistence, capillary, plastic-tip5, glass-tip5 and other sensors as well as portable (or mobile) measuring systems5. New regimes, modes and applications based on analysis of physico-chemical factors and functioning conditions have been suggested. Now even the mini-, semimicro-, micro- or nanovolumes (nanoliters) of the electrode phase can be used.

NEW ELECTROANALYTICAL AND PHYSICO-CHEMICAL RENEWED ASPECTS OF ELECTROCHEMICALLY RENEWED SENSORS BASED ON MERCURY OR AMALGAMS

LADISLAV NOVOTNÝ and PETRA POLÁŠKOVÁ

* University of Pardubice, Faculty of Chemical Technology, nám. Čs. Legií 565, 532 10 Pardubice 19, Czech Republic.
* Charles University, Faculty of Science, Albertov 8, 128 40 Prague 2, Czech Republic. nvt.l@seznam.cz, polaskovap@centrum.cz

Use of purely mechanical renewal of the above-mentioned sensors (electrodes) based on mercury or amalgams results in adequate consumption of the electrode phase, depending on the applied experimental conditions. The ways how to reduce a consumption of mercury or amalgams have been explored and tested. The obtained results outlined, that a combination of the mechanical and purely electrochemical renewal of the electrode surface of HMDE seems to be useful for many electroanalytical as well as physico-chemical applications. This finding is supported by the adequate physicochemical reasons and interpretation of corresponding interfacial behavior of species present in the measured solution.

For example, application of purely electrochemically pretreated HMDE produced analogous sharp cathodic DPV-peaks of 2-aminoanthraquinine 2-AA in 0.05 M BrRo:MeOH 1:1, pH 4.6 at the same depolarization potentials as in the case of application of mechanically renewed HMDE resulting in $\Delta I$ vs. c dependence of a parabolic shape exhibiting a more flat course approaching the linear dependence. It is so probably due to a time-dependent competition between adsorption of 2-AA and other multi-partial electrosorption interactions in the electrode boundary. There is a mixture of present physicochemical (interfacial) processes influencing the actual state of the electrode surface. A reasonable sensitivity and reproducibility outlined a good analytical, biophysical, etc., applicability of the discussed electrochemical renewal.

GRAPHITE FOILS AS WORKING ELECTRODE SOURCE IN AMPEROMETRIC FLOW INJECTION ANALYSIS OF PHARMACEUTICAL MOLECULES

ANDRÉ G. OLIVEIRA, RODRIGO A. A. MUNOZ, and LÚCIO ANGNES*

Institute of Chemistry, University of São Paulo, Av. Prof. Lineu Prestes 748, 05508-000, São Paulo, Brazil luagnes@iq.usp.br

Graphite foils are widely used as a sealing material for high temperature, high-pressure transfer of liquids, gases, steam, chemicals and corrosives, as gaskets material in automotive, petroleum, chemical, paper, and nuclear industries, and as bipolar plates in the fuel cell industry.

A potential application almost unexplored of bare graphite foil is the development of electrochemical sensors, aiming analytical applications. Graphite foils were used as substrate for enzyme immobilization for the confection of biosensors, as electrode for fuel cell, and as substrate to grow carbon nanotubes.

Herein we describe the use of graphite foils as the working electrode in flow systems employing amperometric detection. In our studies, graphite foils were adapted in a flow cell and applied for the determination of pharmaceutical products.

Fig. 1 shows the electrochemical flow cell: It is constituted by two acrylic blocks (A), which are tighten by two screws (B). A polyethylene foil (C) containing a hole (G), which is positioned between the two blocks, over the graphite foil (D), used as working electrode. In the outlet channel of the cell, a stainless steel tube (E) works as the auxiliary electrode. Near to this tube, in the outgoing channel was positioned the miniaturized Ag/AgCl electrode (F). The arrows indicate the inlet and outlet of the solution. Polyethylene tubes are used to conduct the solution to the cell.

Prior to the electrochemical flow cell, there is an injection valve at which a sample loop with a fixed volume is injected in the flow system. The solution was propelled by the gravity force by placing a vessel containing electrolyte at 1 meter height and controlling the flow rate pinching a Tygon tube which was inserted in the line.

Cyclic voltammetry was employed to investigate the
electrochemical oxidation of acetaminophen and ambroxol at graphite foil electrodes. The good performance for the alternative electrode allowed the use of amperometry in a FIA system. The first experiments were carried out to optimize the FIA system for the amperometric determination of acetaminophen.

The best conditions were +0.7 V as the working potential, flow rate of 2 mL min$^{-1}$, sample loop of 200 µL, and 0.1 mol L$^{-1}$ KCl as the supporting electrolyte. Fig. 2 shows the amperometric responses for eighteen consecutive injections of 1×10$^{-4}$ mol L$^{-1}$ acetaminophen under the optimized conditions. The relative standard deviation was 2.7 %.

These preliminary results show the potential application of graphite foils as electrochemical sensors for FIA systems. The advantages of using such material as electrode are its low cost, which would allow the production of disposable electrodes. The determination of ambroxol using the proposed analytical system is now been optimized. Graphite foil electrode may also be used as a substrate for electrodeposited catalysts to produce sensors with improved selectivity and sensibility.

Acknowledgement to CNPq, FAPESP, and IM 2C for financial support. Graphite foils were a gift from Longteng Sealing, Shandong, China.

REFERENCES

Carbon nanotubes (CNT) have been attracting considerable attentions over the last decade due to their remarkable mechanical and electrical properties. CNTs have a novel structure, highly accessible surface area, low resistance, and high stability. It has been experimentally shown that composites based on the combination of CNT with an insulating matrix improve the electric conductivity as well as the mechanical properties of the original polymeric matrix. The transition from an insulating to a conducting composite is a function of the CNT loading. When a first network is developed throughout the insulating matrix, the composite resistivity lowers by several orders of magnitude. When this drop occurs, it is called percolation threshold. Although the variation of the mechanical and electrical properties of composite containing different CNT percentages, has been investigated and evaluated by other authors, their influence in the electrochemical properties of composites has not received the same attention.

The aim of the present study is to optimise the CNTs loading in the insulating matrix (resin epoxy) by means of electrical and morphological measurements and then to determine how the electrical properties affect the analytical response of the composites when they are used as amperometric sensors.

The multiwall carbon nanotubes used in this study (MWNT, purity > 95 %, length 5−15 µm, OD 10−30 nm) were supplied by SES Research (USA). The polymer matrix consisted of Epotek H77 with its corresponding hardener (Epoxy Technology, USA).

Previously to the fabrication of different composites, the MWNTs were pre-treated with nitric acid (HNO$_3$) for improving their homogenization. Composites with different MWNT loading were tested through the evaluation of their electrical, morphological and electrochemical properties.
